

# Do protected areas reduce deforestation?

A global assessment with implications for REDD

Andrew Nelson  
Kenneth M. Chomitz

# The REDD challenge: what can be done?

- What is known about *how* to reduce deforestation?
- How can we rapidly and reliably learn what works and what doesn't?

# Protected Areas (PAs) – a REDD analog

PAs are often intended to reduce deforestation – motivated by biodiversity conservation

Most REDD interventions will involve restrictions on allowable forest uses – so legal, economic, and enforcement issues are similar to PAs.

PAs have absorbed lots of effort, money, real estate...

But do they actually reduce deforestation?

# Protected areas occupy a large and growing portion of Earth

1.4M sqkm, 20%

2.8M sqkm, 39%

0.2M sqkm, 9%

0.4M sqkm, 16%

0.3M sqkm, 9%

0.5M sqkm, 13%

15% of the tropical forest was “protected” in year 2000

This has expanded to over 27% in 2008

# Land under indigenous control: 2000 and 2008

0.36M km<sup>2</sup>, 5.1%

0.85M km<sup>2</sup>, 12%

(Based on IUCN classification– data only for Latin America)

# Large economic investments in PAs

- GEF 1991-2009 reports:
  - \$1.6 billion direct investments
  - \$4.2 billion cofinancing  
(much is via World Bank)
- Potentially large opportunity costs

# PAs: Paper parks, conservation cornerstone, or exclusionary scheme?

Three stylized views:

- PAs effectively conserve forests; nothing else works as well

vs

- Underfunded PAs are unable to defend against depredation, and so are 'paper parks'

vs

- PAs defend *too* well, excluding poor and local people

# Controversy persists due to lack of evaluation

- Few rigorous evaluations of environmental impacts
- Almost none of social impacts
- Reasons for lack of evaluation
  - Naïve evaluations are misleading; must account for confounding influences
  - Dearth of data

# Some protected areas appear to be effective

## Bia National Park, West Ghana

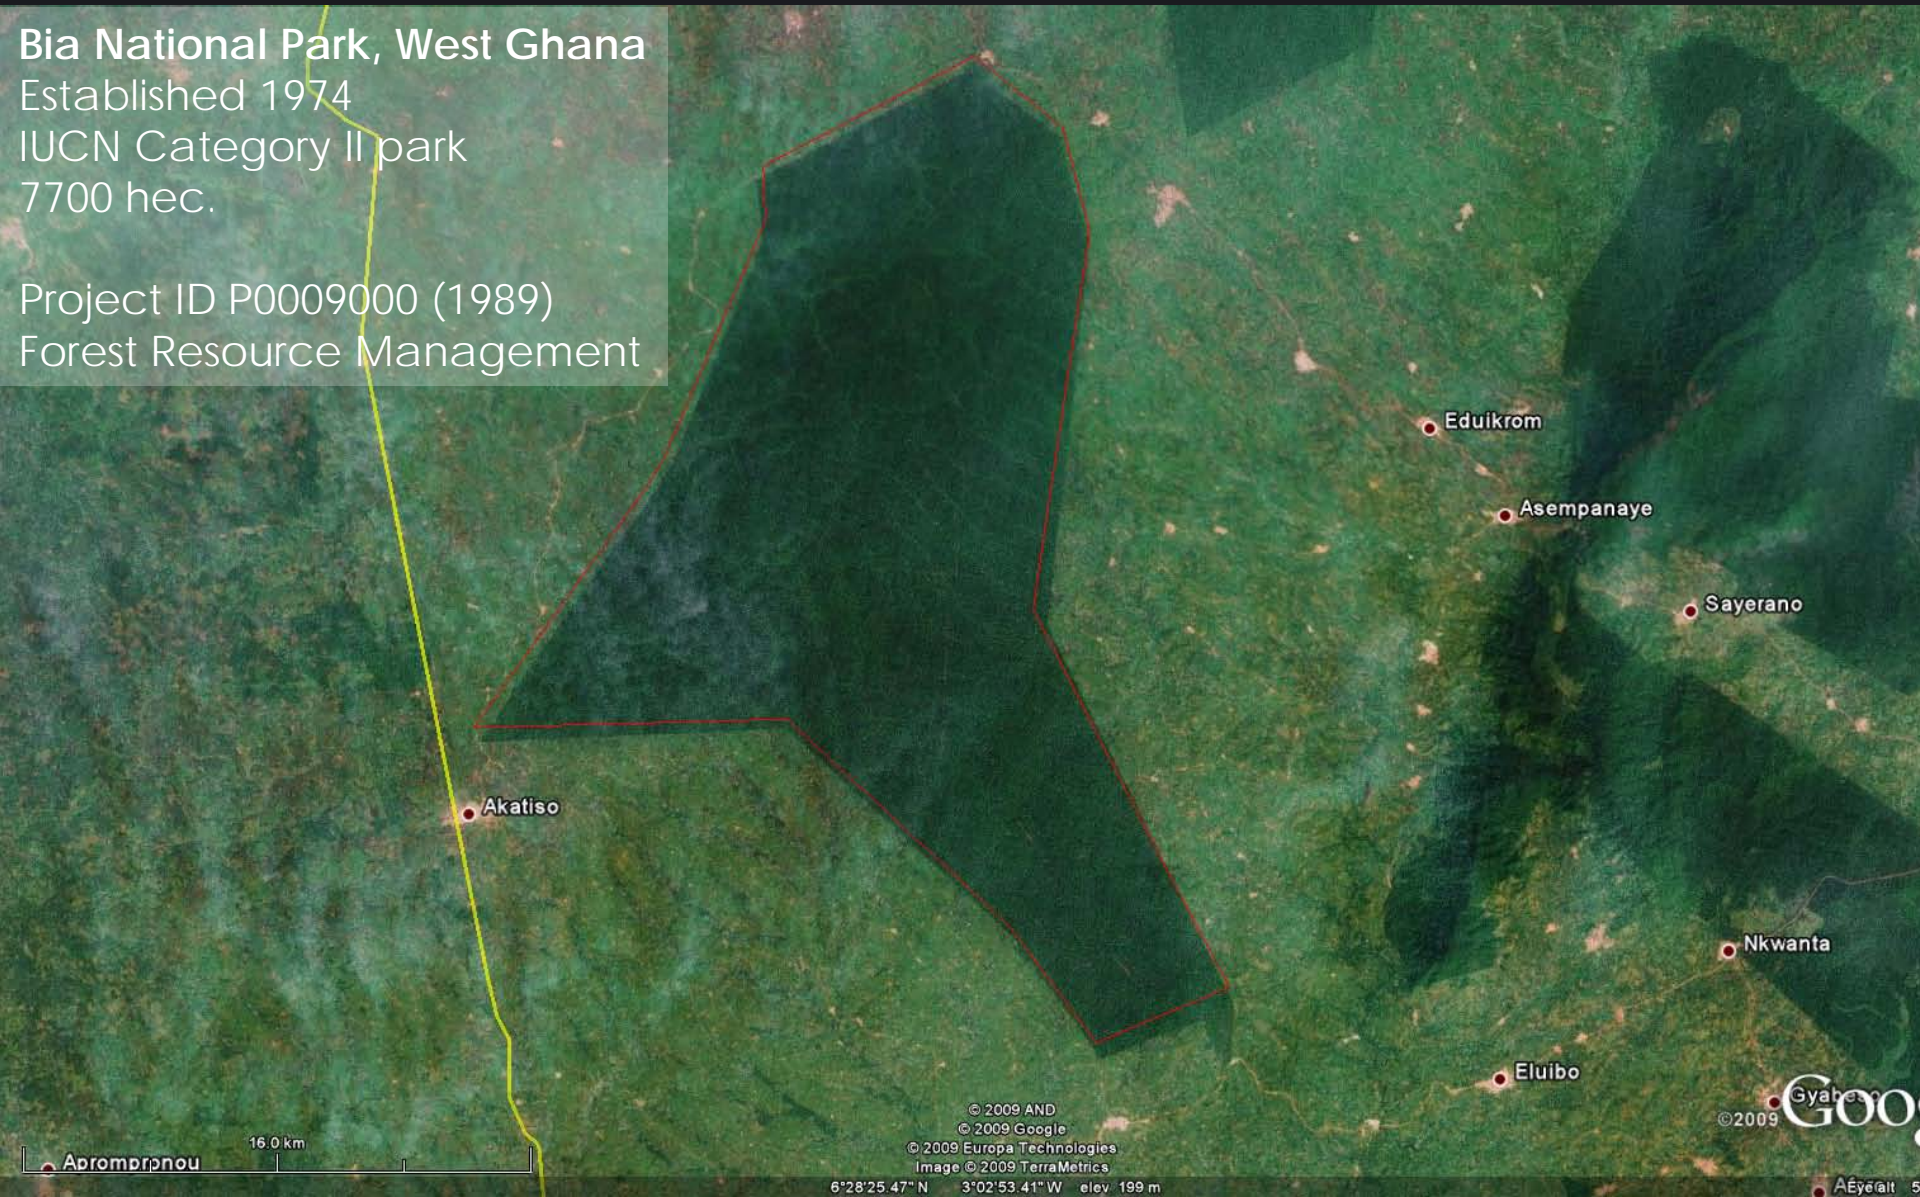

Established 1974

IUCN Category II park

7700 hec.

Project ID P0009000 (1989)

Forest Resource Management

# Clearing and fires in Rondonia, Brazil

**Castanheira, Rondonia, Brazil**

Established 1995

IUCN Category VI park

9,700 hec.

Project ID P058503 (2003)

Amazon 2000

but protection may be due to terrain, not law

**Gunung Leuser, Indonesia**  
Established 1980  
IUCN Category II park  
792,675 hec.

Project ID P003907 (1988)  
First Forestry Institutions

# Fires: The only consistent, high resolution global measure for 2000-2008

0.37M sqkm

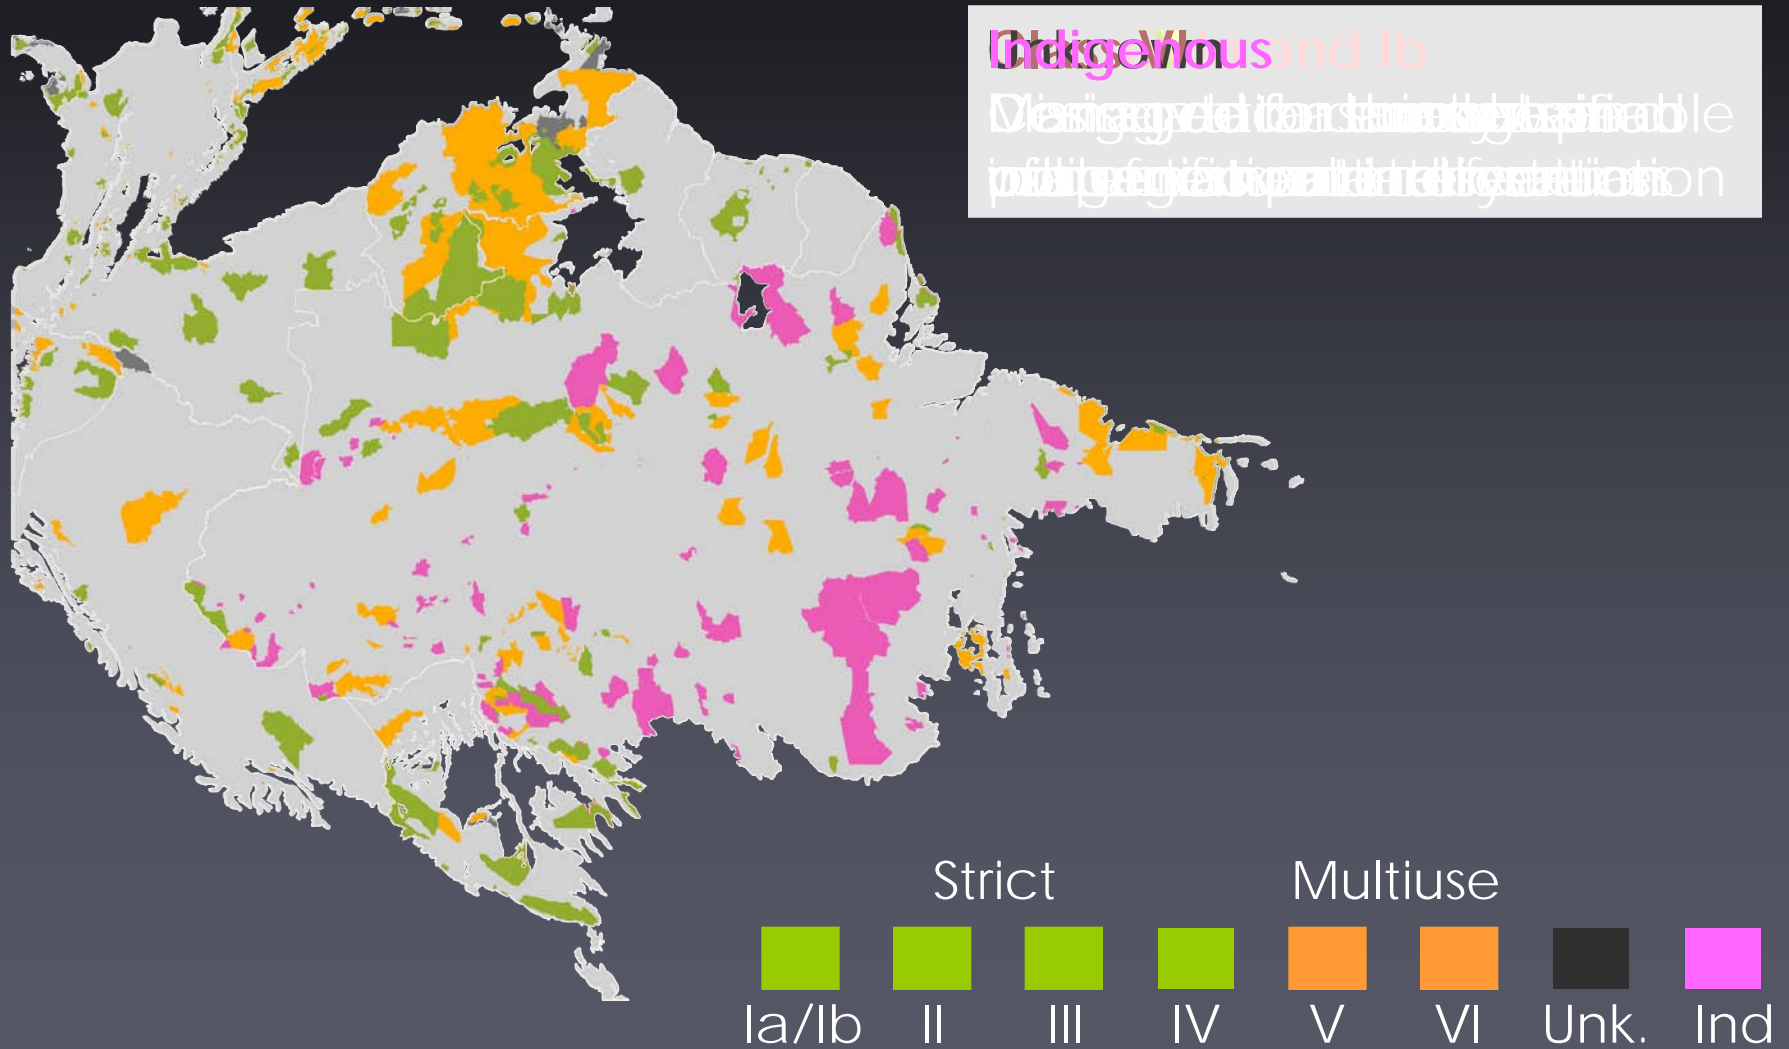

0.14M sqkm

0.19M sqkm

Some 0.7M sqkm of tropical forest fire affected area (2000 to 2008)

# Protected area management categories

# Mean impact: all PAs established before 2000

Avoided fire area as a percentage of the total protected area  
 Avoided fire % = Non-protected fire % - Protected fire %

Region	Protection	Naïve comparison	Controlled comparison
L. America	Strict	5.8%	2.7% - 4.3%
	Multiuse	4.4%	4.8% - 6.4%
	Indigenous	5.9%	16.3%-16.5%
Africa	Strict	4.2%	1.0% - 1.3%
	Multiuse	3.1%	0.1%-3.0%
Africa	Strict	(post 1990 PAs)	4.4%-5.5%
Asia	Strict	1.2%	1.7% - 2.0%
	Multiuse	1.8%	4.3% - 5.9%

These % areas are for the 8 year period 2000-2008

# Mean impact: all PAs established before 2000

# Conclusions

Protected areas generally have significantly lower deforestation than comparable non-protected areas

Multi-use protected areas generally provide at least as much deforestation reduction (in absolute terms) as strict protected areas.

Indigenous areas have a very high protective impact

Rigorous evaluation methods can give very different results from naïve approaches

# Caveats

Fires are an imperfect proxy for deforestation

We don't measure degradation

Protected areas serve many other functions other than deforestation protection

Establishment of PAs in remote areas may be an effective way to prevent future deforestation as pressure increases
